

ALMAで探る彩層磁気リコネクションの物理

=初めて散逸スケールをイメージングで
見ることができるかも

磯部洋明

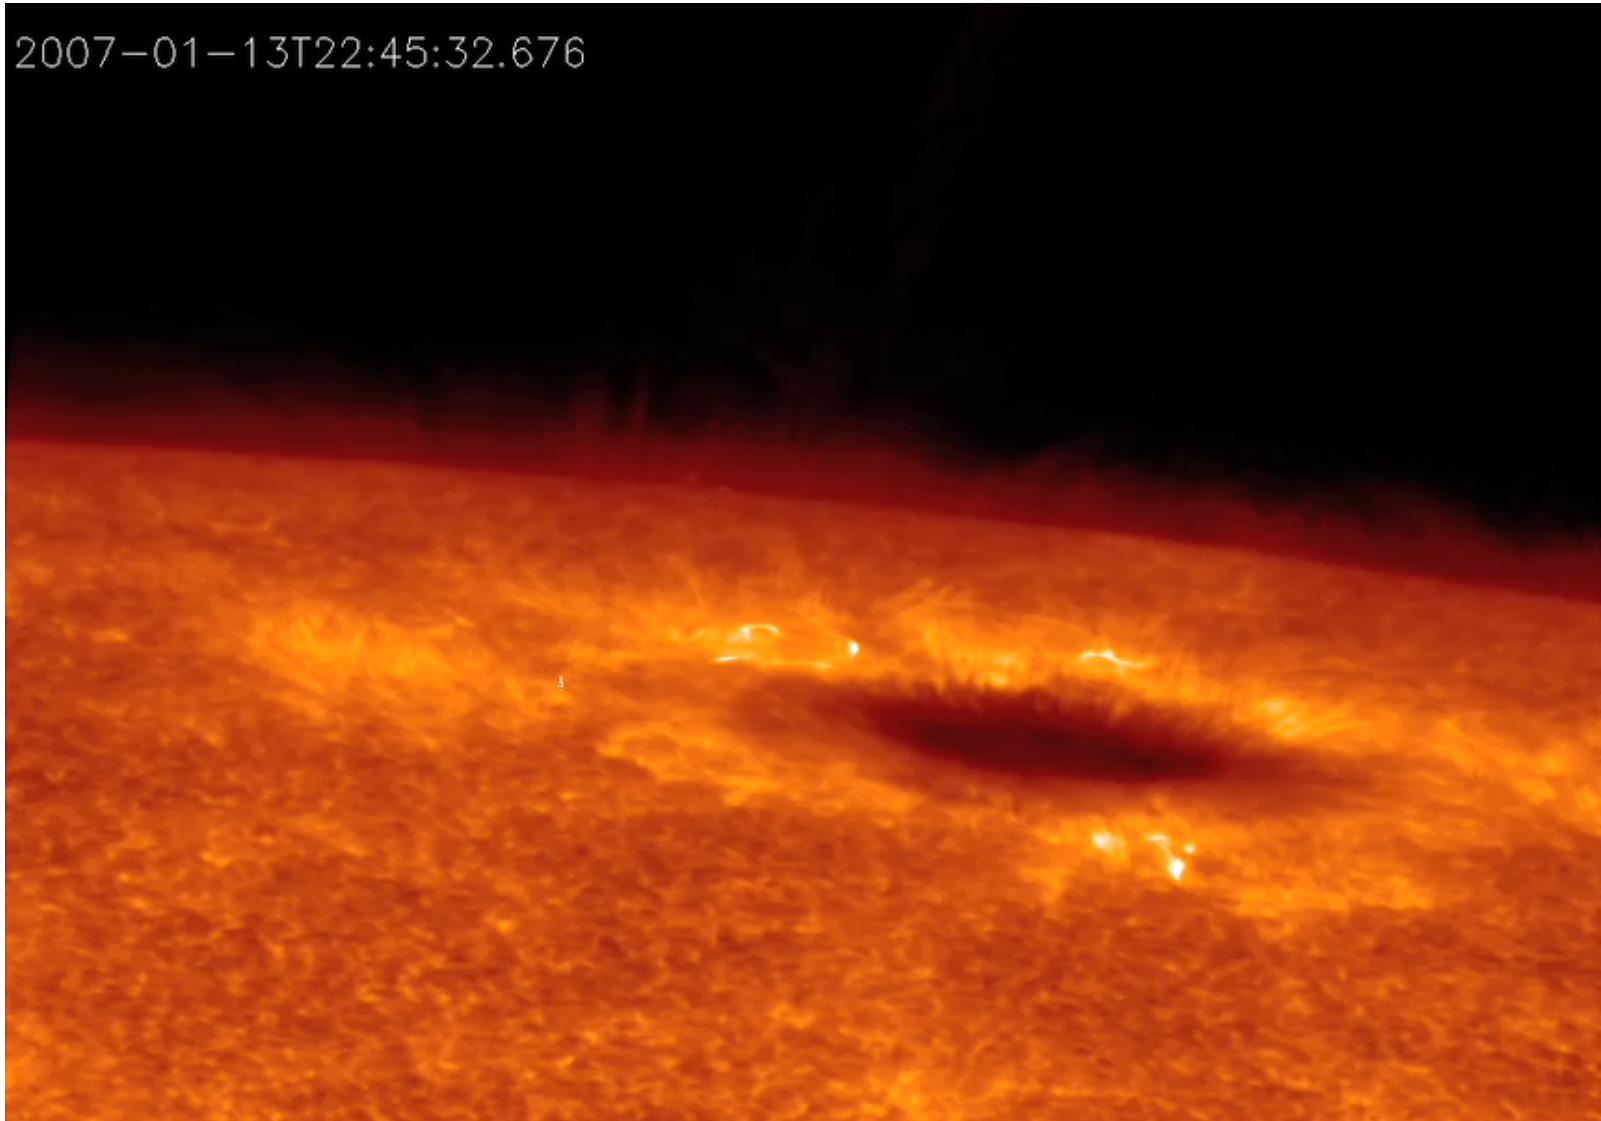

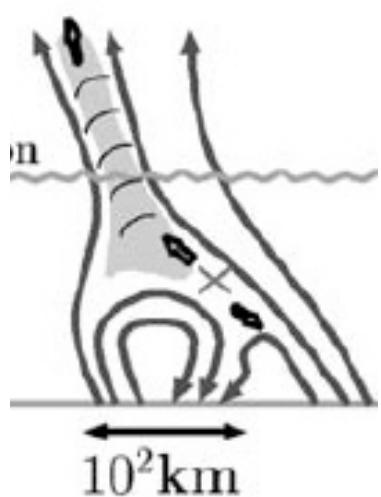

京都大学宇宙総合学研究ユニット

概要

1. 彩層磁気リコネクションの何が面白いか
2. 彩層プラズマのおさらい(中性粒子の効果)
3. 磁気リコネクション研究の最近の進展
4. ALMAで期待されること

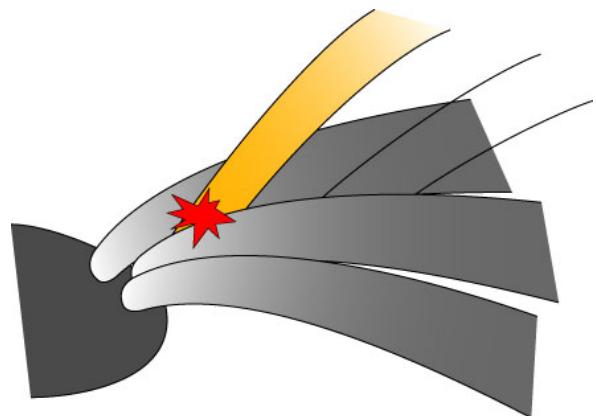

彩層ジェット

2007-01-13T22:45:32.676

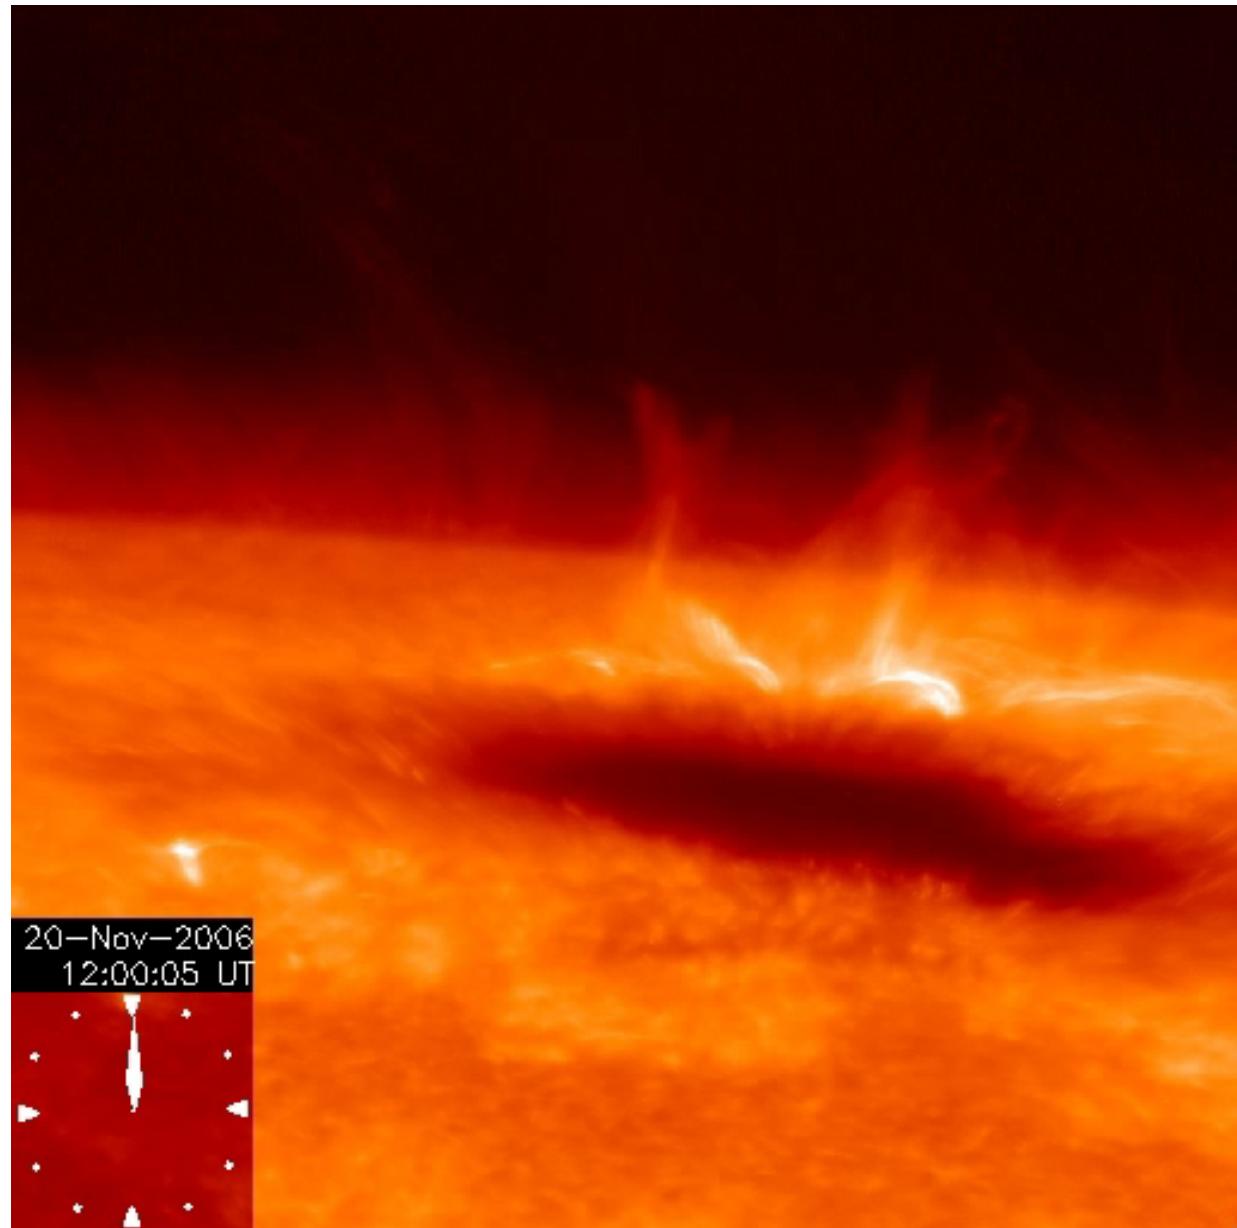

Shibata+07

黒点半暗部ジェット

Katsukawa+07

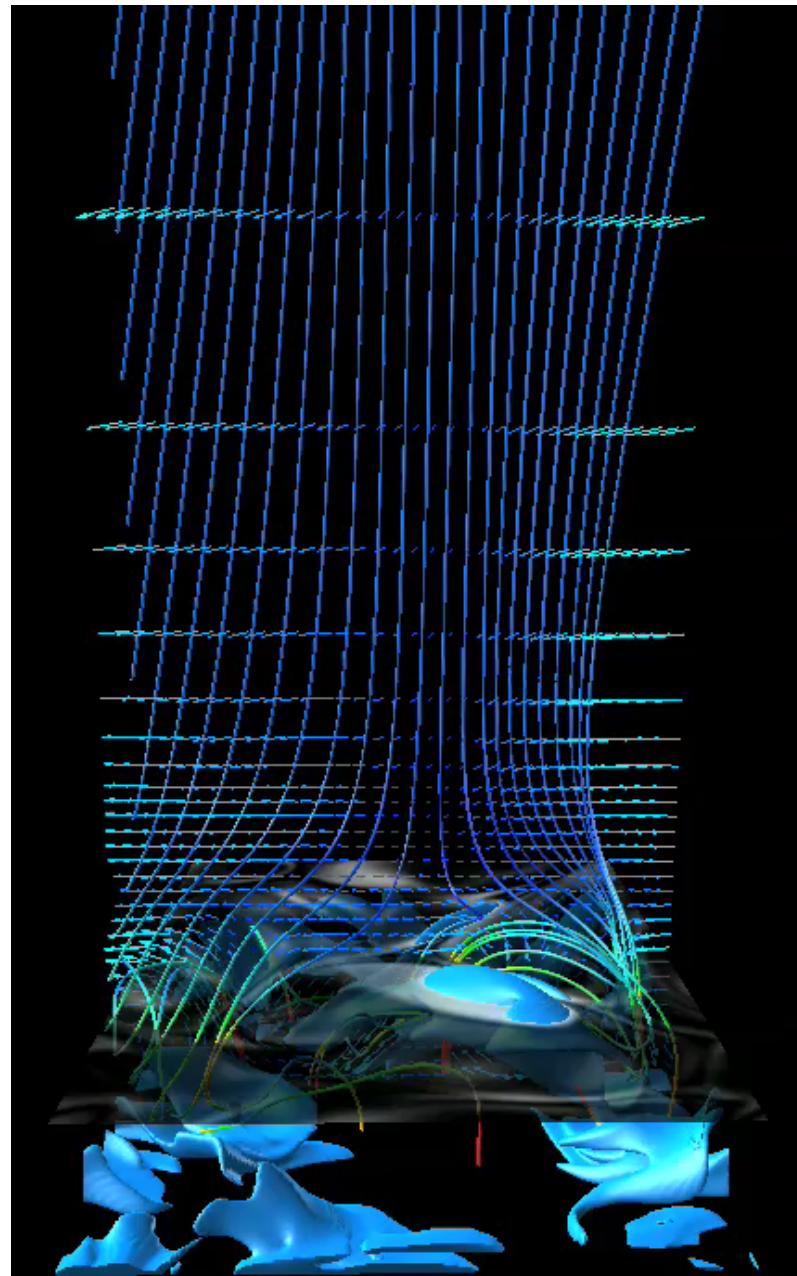

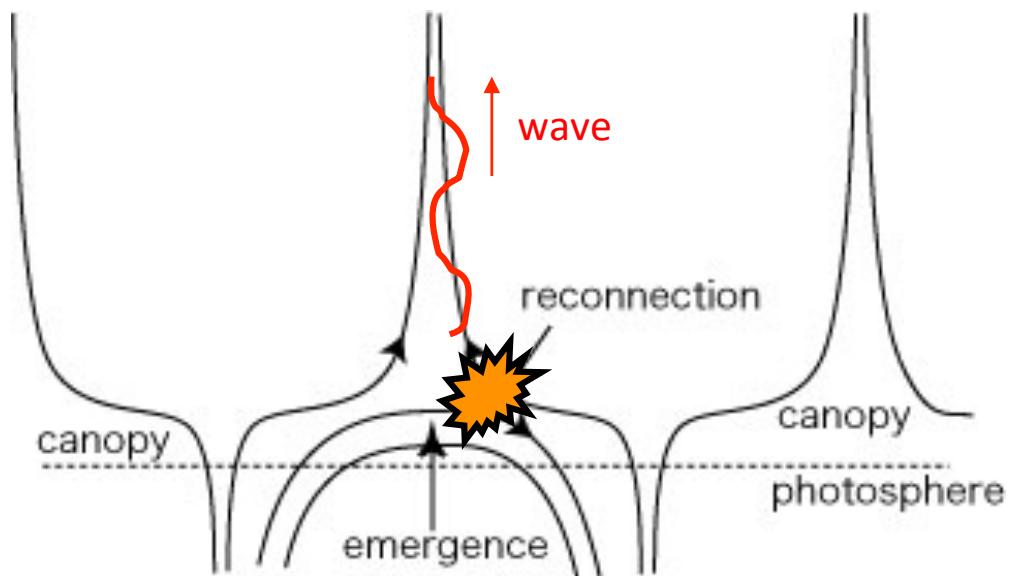

...が、リコネクションの
現場は深すぎてみえな
い？（一本講演）

彩層で磁気リコネクション

=>コロナヘジットや高周波波動供給

=>コロナ加熱、太陽風加速に重要(かも)

Isobe+08

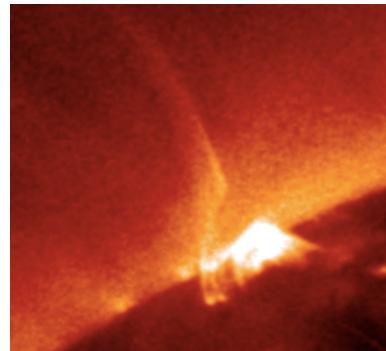

コロナ～彩層のリコネクション現象

サイズは違うがMHD的には似ている(スケールフリーだから当然)
 (ミクロな)プラズマパラメータが全然違う

X-ray jet (コロナ)

~100,000km

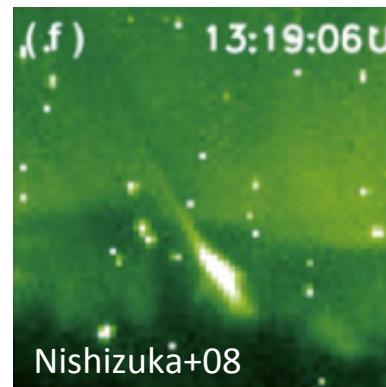

完全電離、ほぼ無衝突

EUV jet (彩層上部～遷移層)

~ 10,000 km

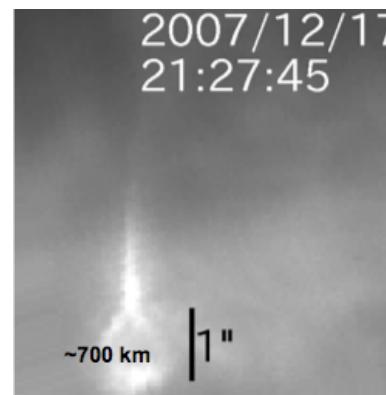

中途半端電離、中途半端衝突

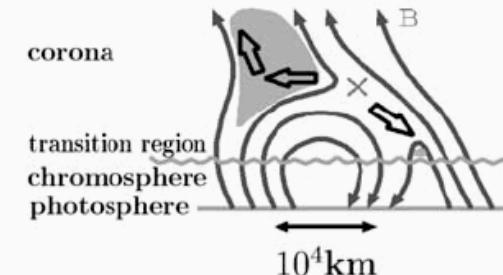

彩層ジェット

~1000km

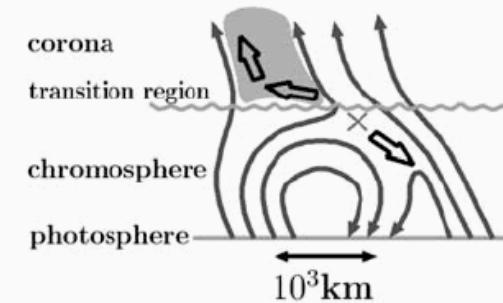

弱電離、完全衝突

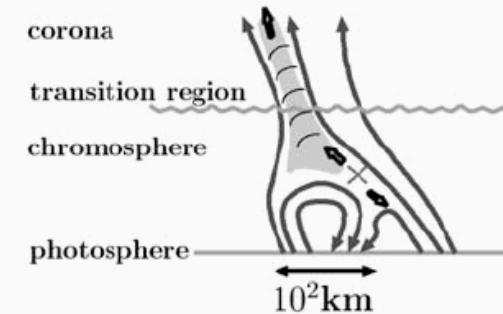

A X-ray Jets/SXR microflares

B EUV Jets/EUV microflares

C Spicules Jets/Photospheric nanoflares

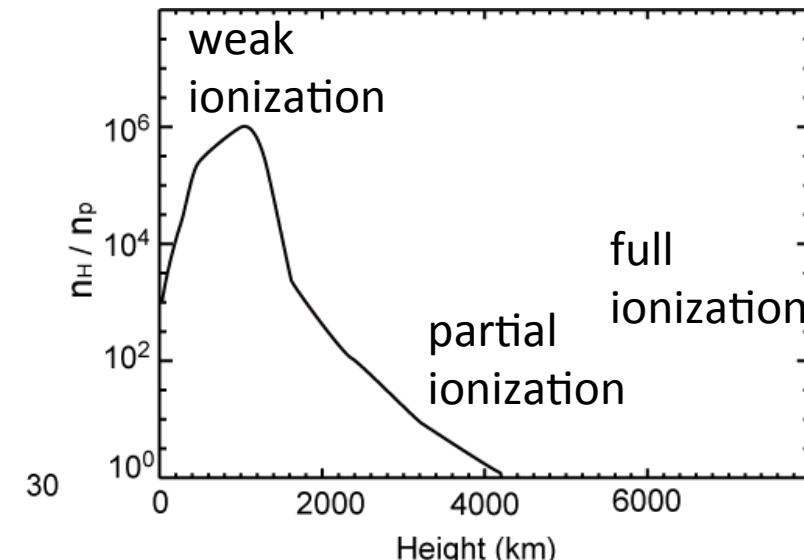

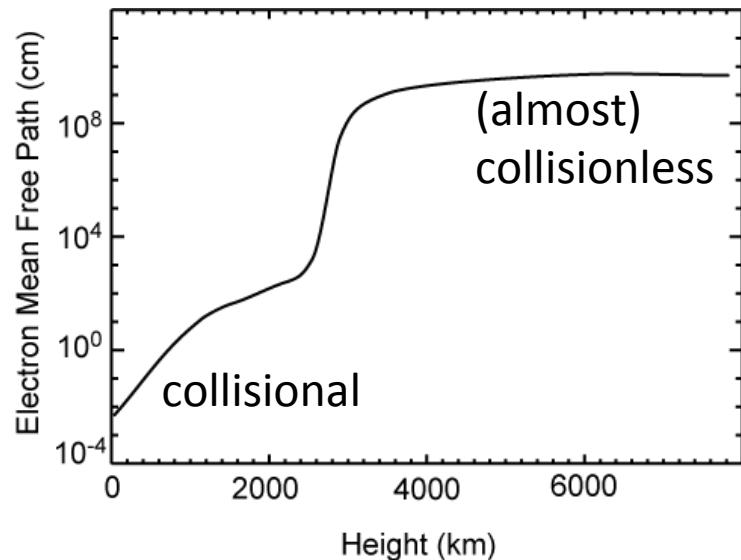

Shibata+07

彩層磁気リコネクションの何が面白いか

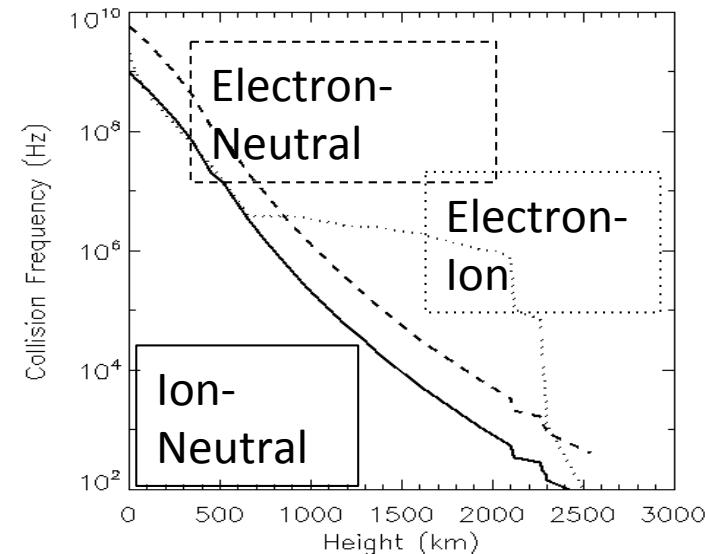

- 彩層でリコネクションがドライブする多様な現象
- コロナ加熱、太陽風加速への寄与(リコネクションに伴うエネルギー分配。特に波にどれくらいいくか)
- コロナとは違うパラメータ(弱電離、完全衝突)だが大局的(MHD的)な描像が似ている。リコネクションの物理は同じか？
- 他天体で似たようなプラズマ環境での磁場散逸への興味。分子雲、原子惑星系円盤...後述

2. 彩層プラズマのおさらい

VAL-C model + smooth extrapolation to the corona

- e-n collision dominates in lower chromosphere (\Rightarrow weak ionization)
- e-i collision dominates in upper chromosphere (\Rightarrow partial ionization)

中性粒子の効果

$$\frac{\partial B}{\partial t} = \nabla \times [V_n \times B - \frac{J \times B}{en_e} + \frac{(J \times B) \times B}{c\nu_{ni}\rho_n} - \eta J]$$

Advection Hall Ambipolar Ohmic

Ambipolar/Hall is important in small scale ... important in reconnection!

$$V_n \times B < \frac{(J \times B) \times B}{c\nu_{ni}\rho_n} \quad \rightarrow \quad L < \frac{V_{An}\rho_n}{\nu_{in}\rho_i} \approx 1-10\text{ km}$$

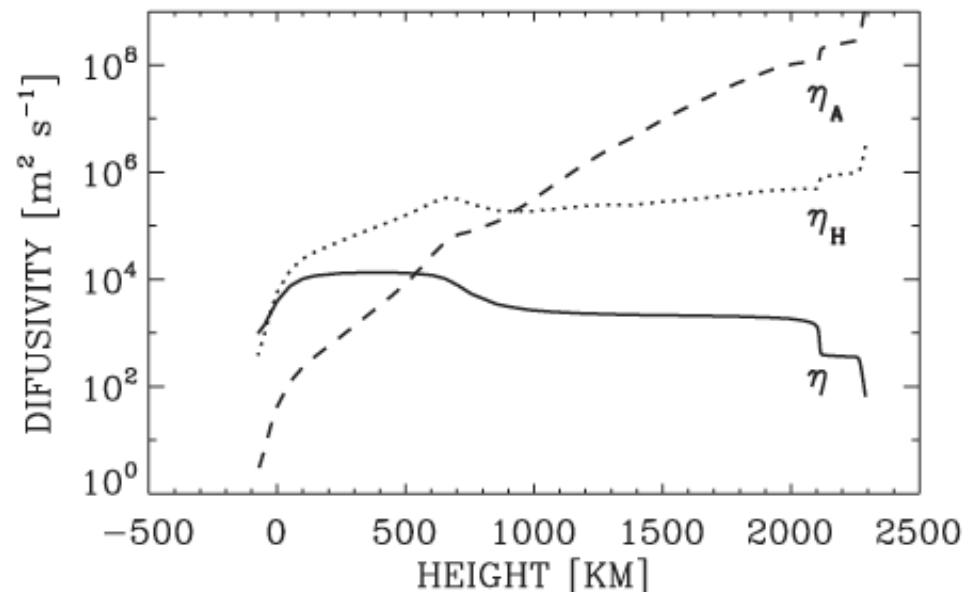

$$\text{Ambipolar/Hall} = \omega_{ci}/\nu_{in}$$

ω_{ci} : Ion-cyclotron freq $\propto B$

ν_{in} : Ion-neutral collision freq $\propto n$

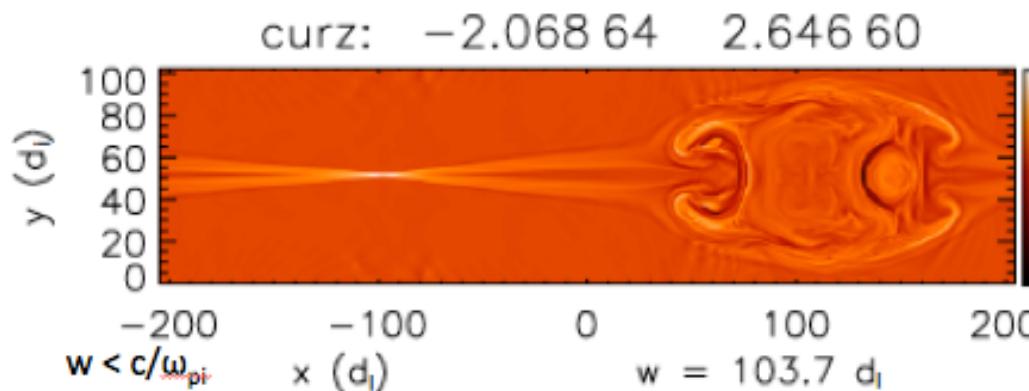

下の方はHall dominant

上の方はambipolar dominant

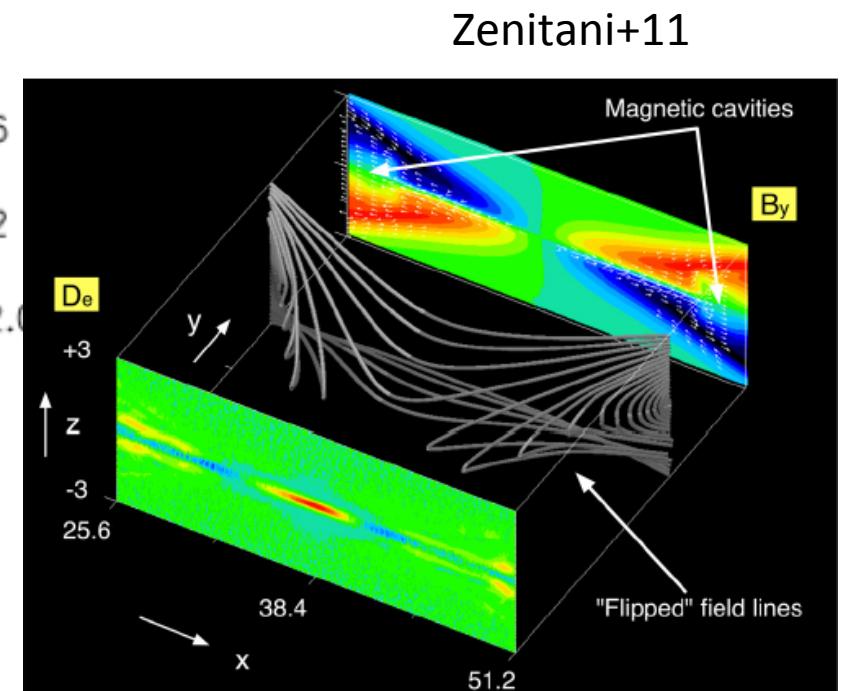

Hall reconnection

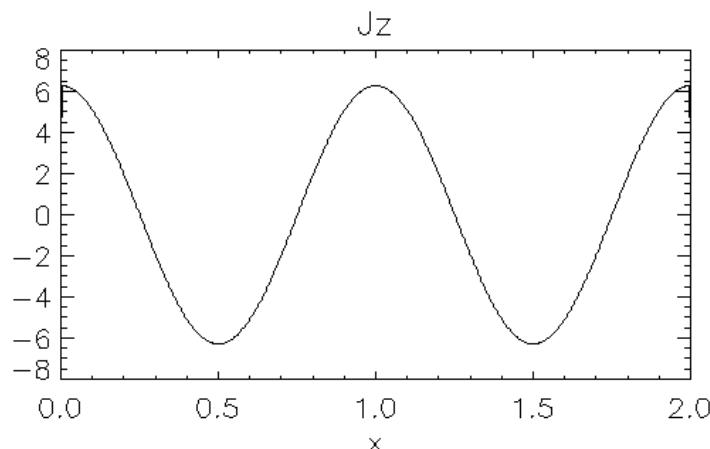

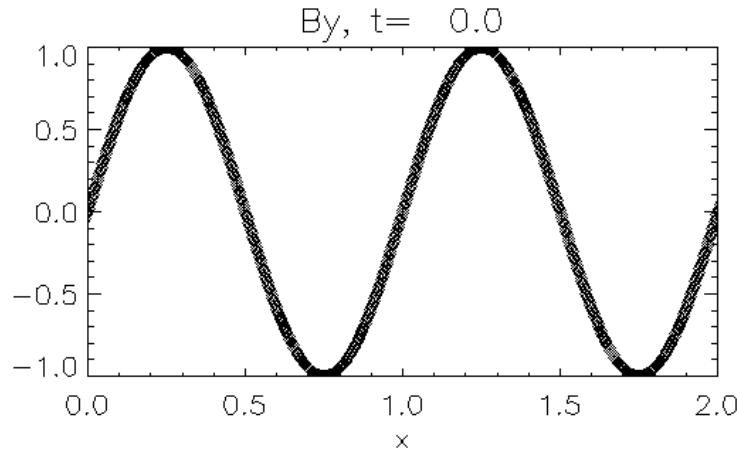

- 電流シートがイオン慣性長 $d_i = c/\omega_{pi}$ より薄くなると起きる
- 磁場の四重極構造と局在化した散逸領域(ペチェック"的"リコネクション)
- 弱電離の場合は実効的なイオン慣性長が $(\rho_n/\rho_i)^{1/2}$ 倍(光球で1-10km)になる

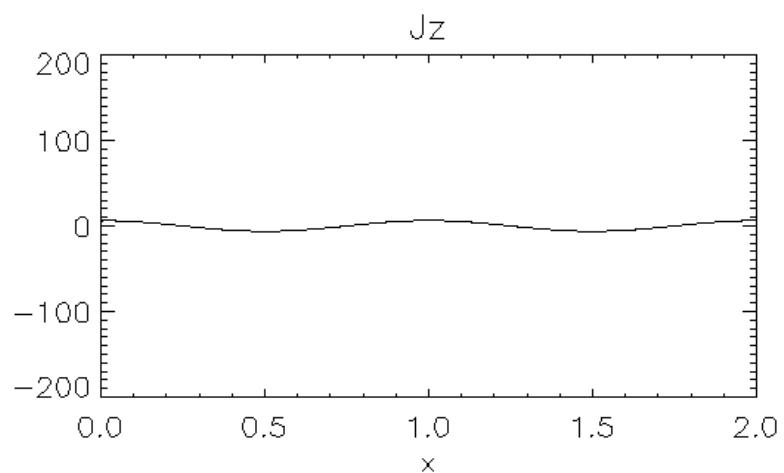

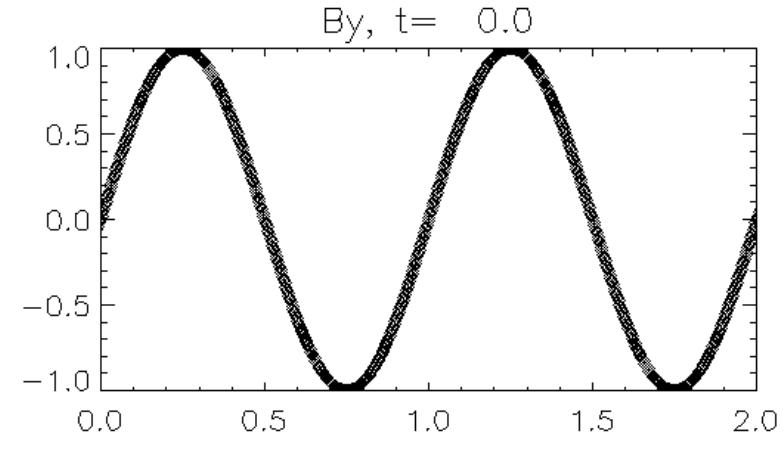

Cassak+05

Current sheet thinning by ambipolar diffusion (Zweibel-san's talk)

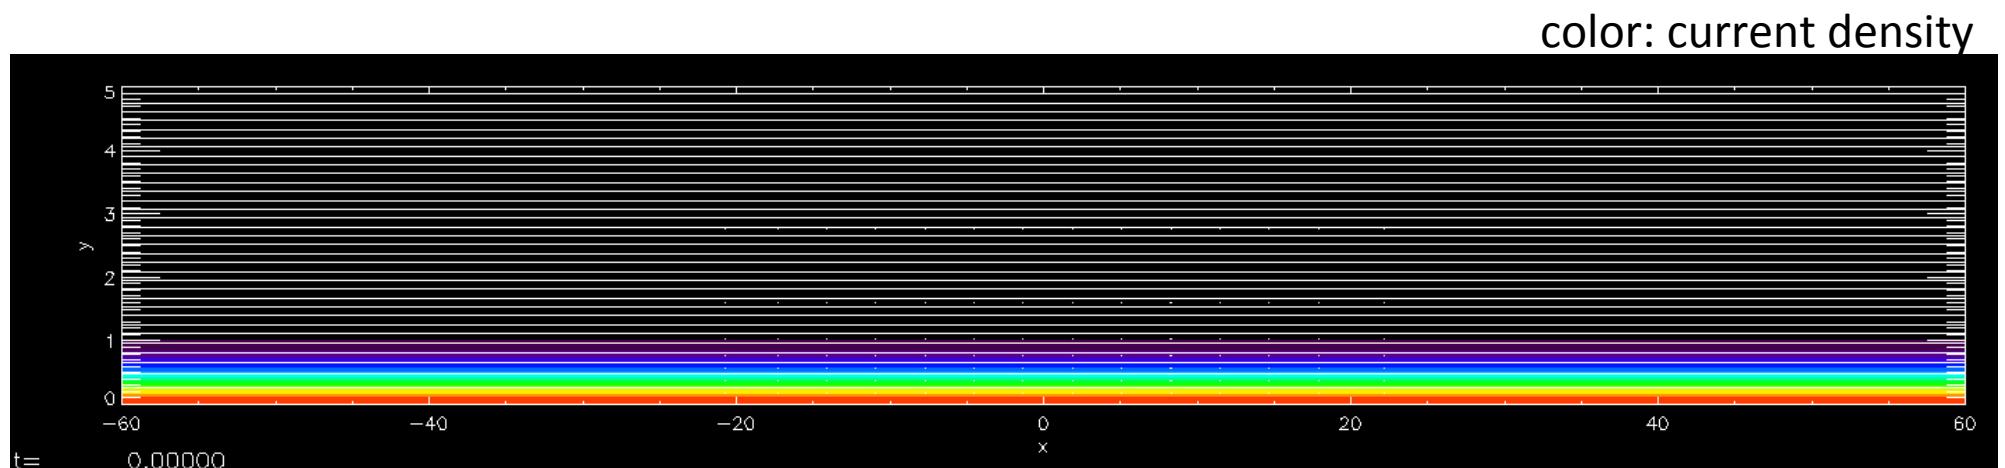

Only resistive diffusion

Only ambipolar diffusion

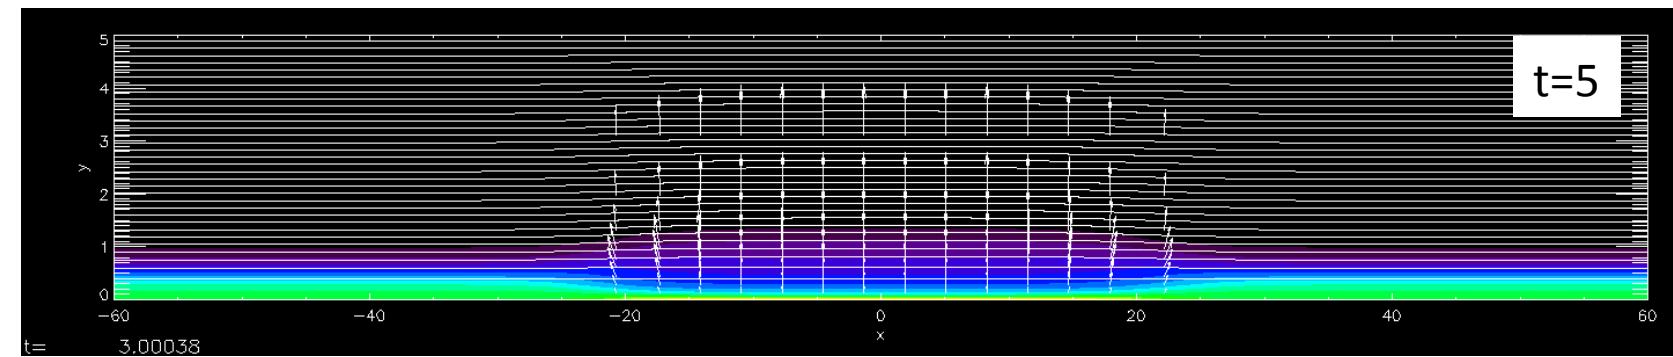

Effect of non-uniform ambipolar diffusion

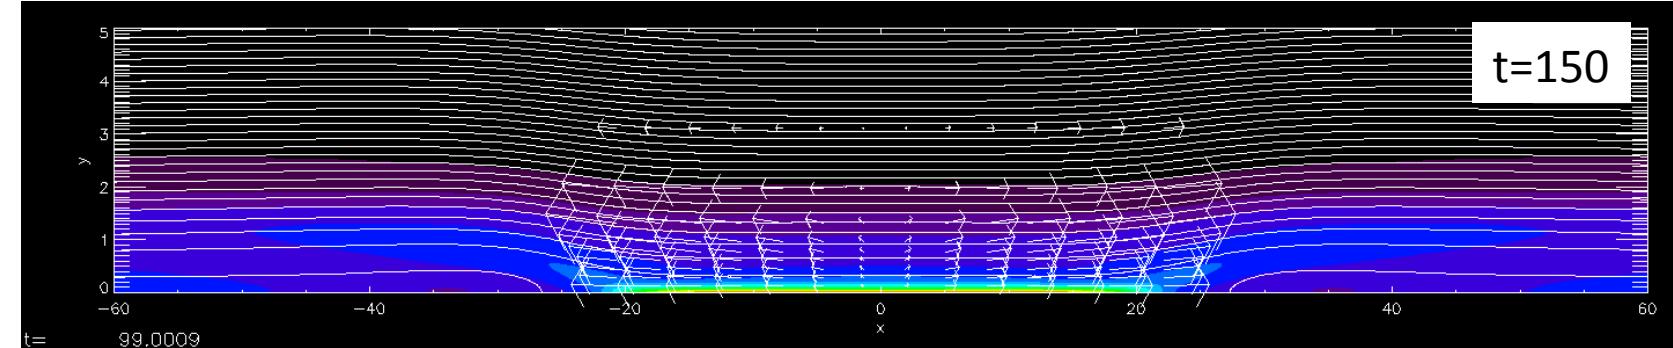

↔
Ambipolar diffusion $\neq 0$

Ambipolar diffusion localized in $x < \pm 20$
Ohmic resistivity is uniform

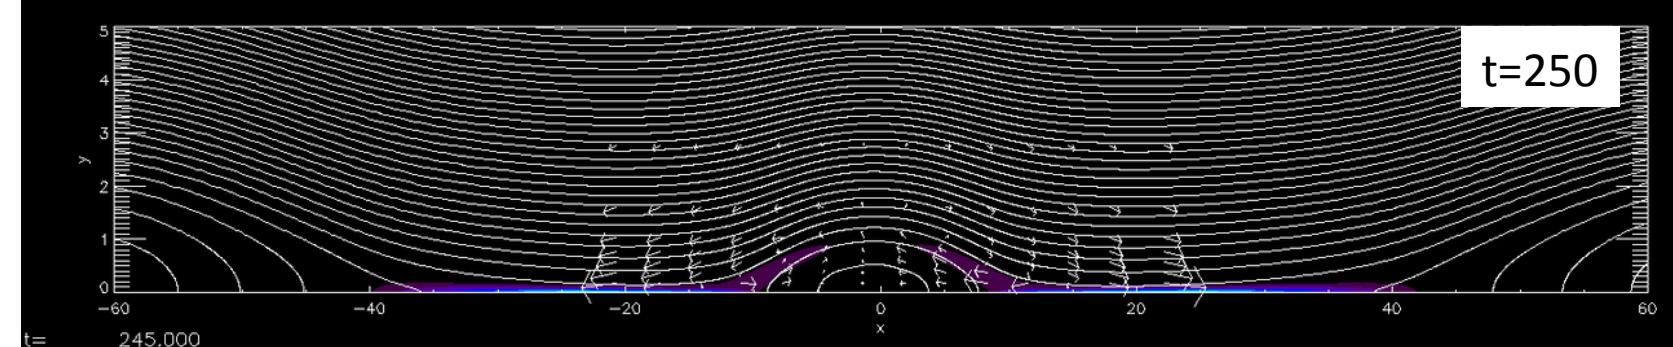

Thinning

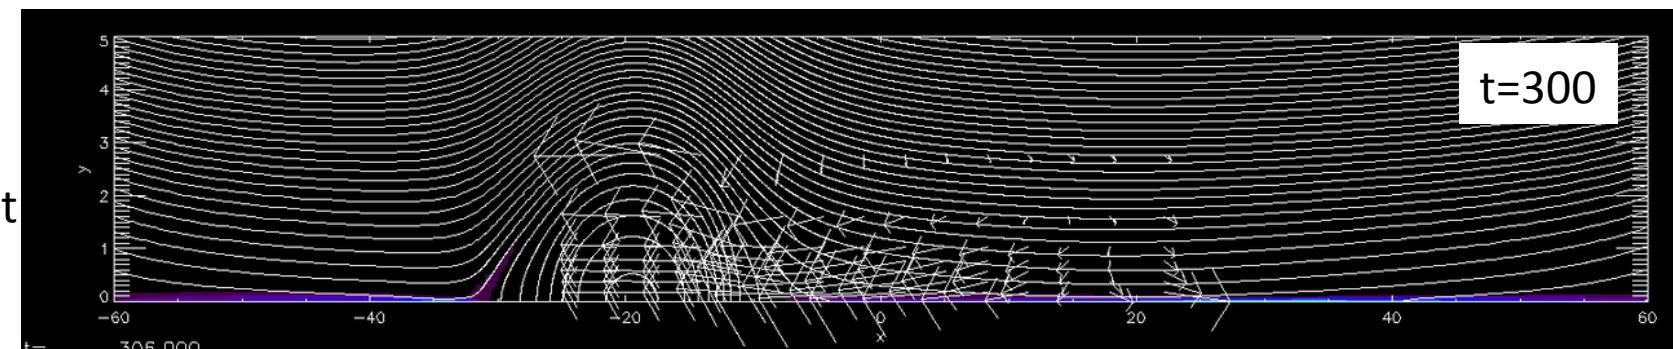

Sweet
-Parker
reconnection

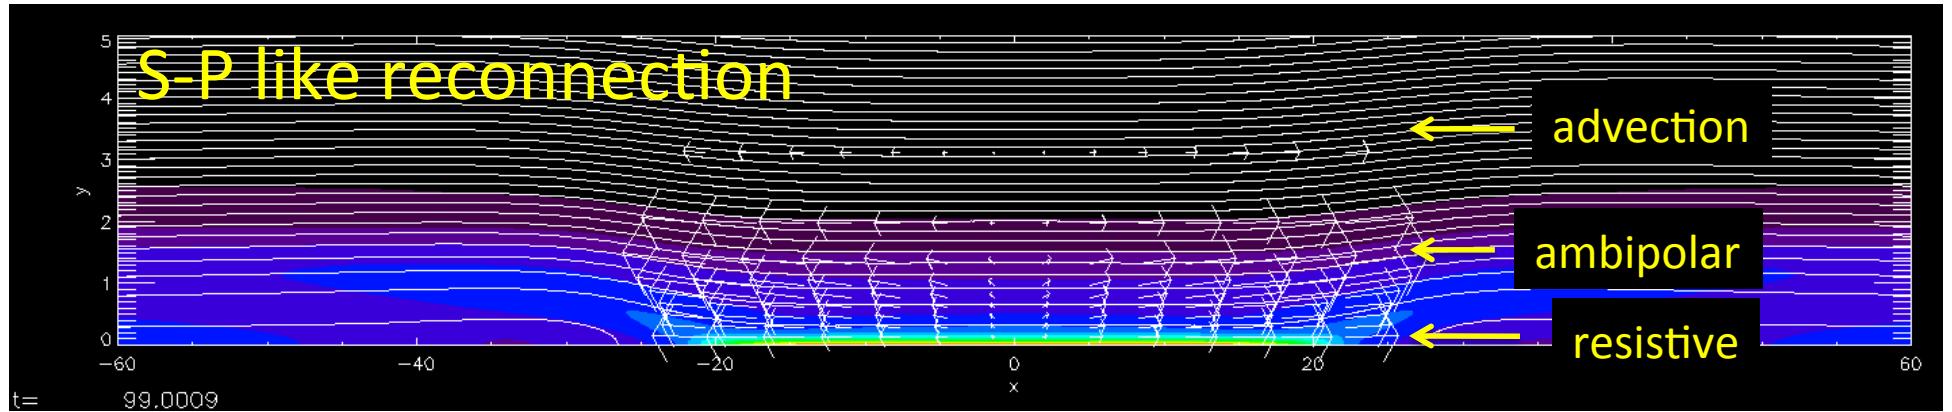

Tearing and
island
formation

Island ejection
and time-
dependent fast
reconnection

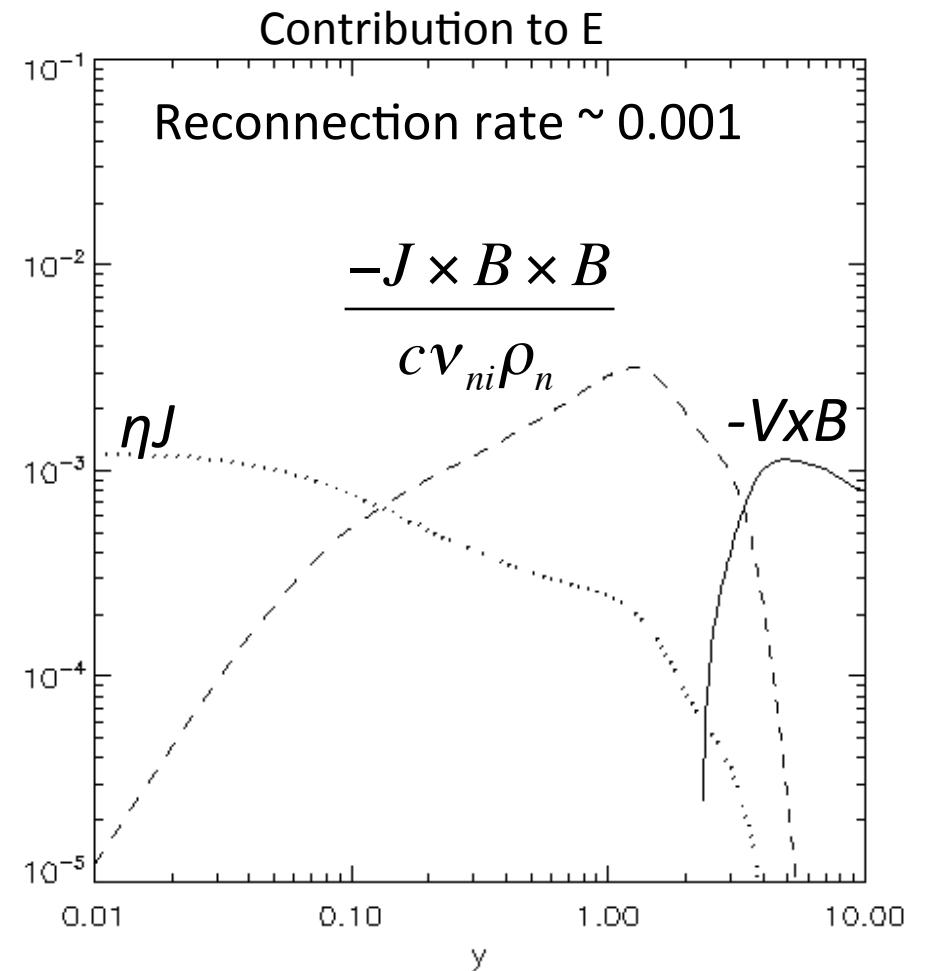

In Sweet-Parker-like stage, the reconnection region consists of **3 layers**:

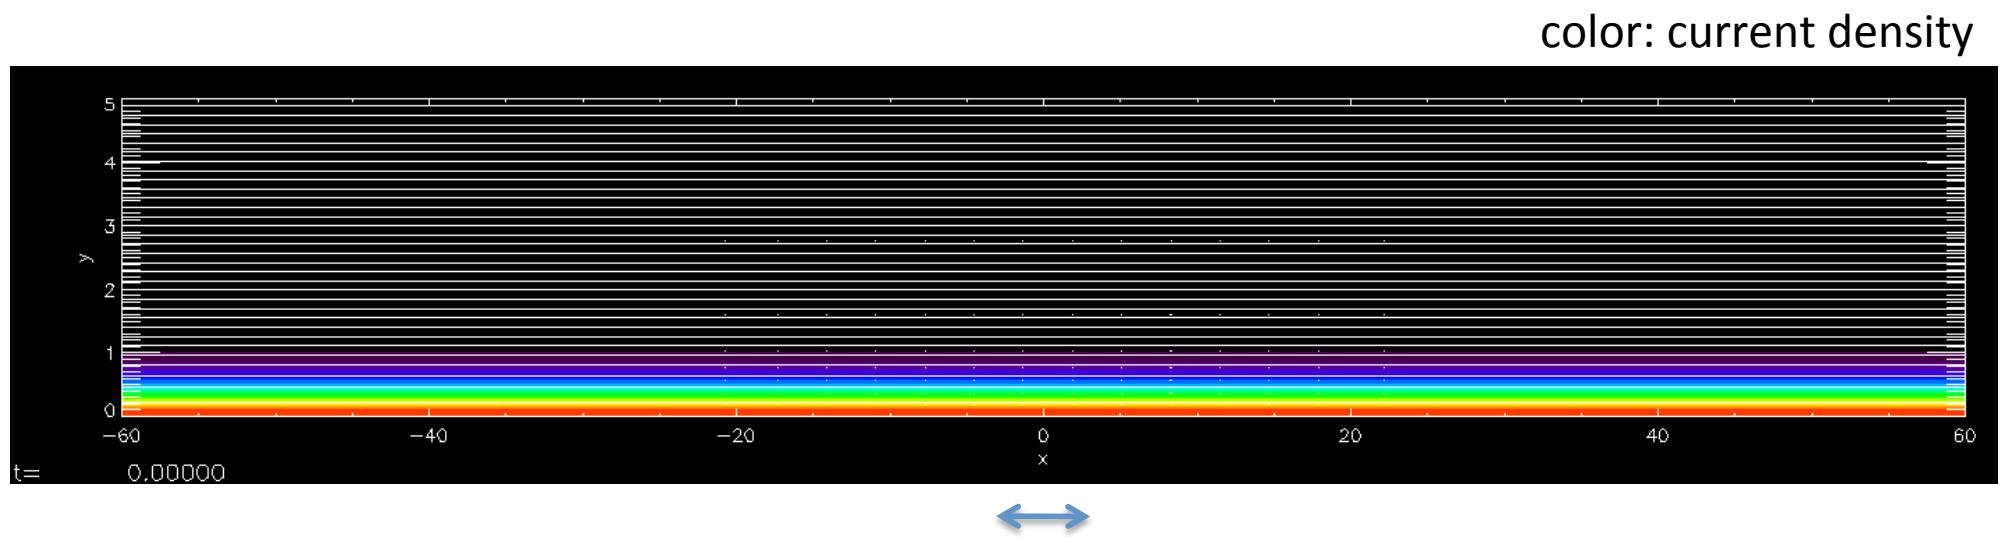

- resistive-dominant inner current sheet
- ambipolar-dominant outer current sheet
- advection-dominant inflow region

Ambipolar diffusion causes plasma heating
 \Rightarrow outflow driven by gas-pressure gradient
from the ambipolar layer

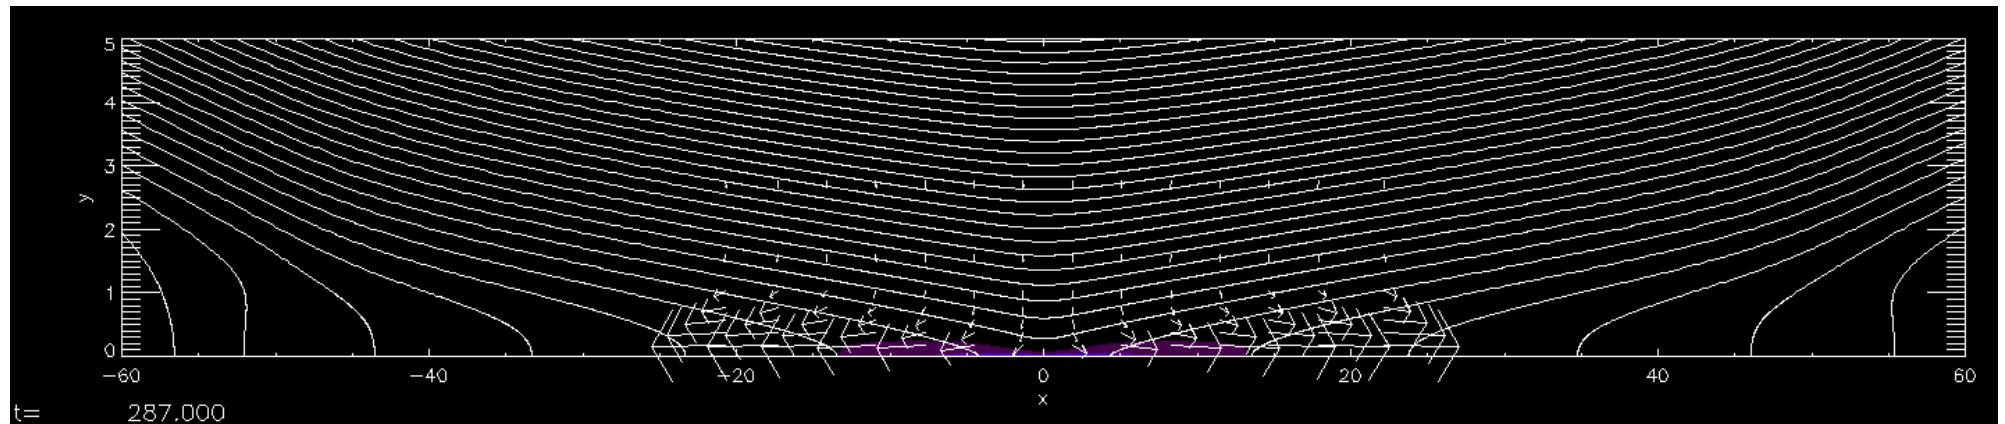

Note: two-fluid treatment is necessary to quantitatively address the (ion-dominant) outflow from resistive layer

Petschek-like regime

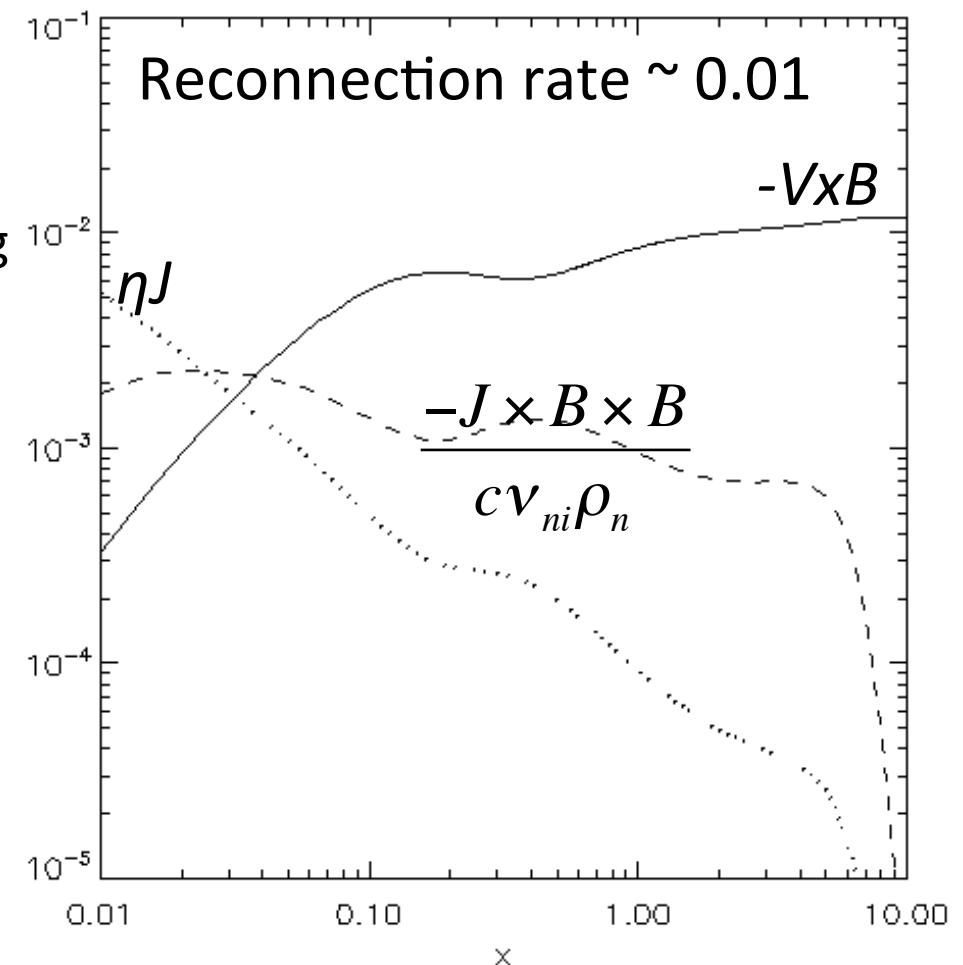

Ambipolar diffusion uniform + enhanced in $x < \pm 2$
Uniform resistivity

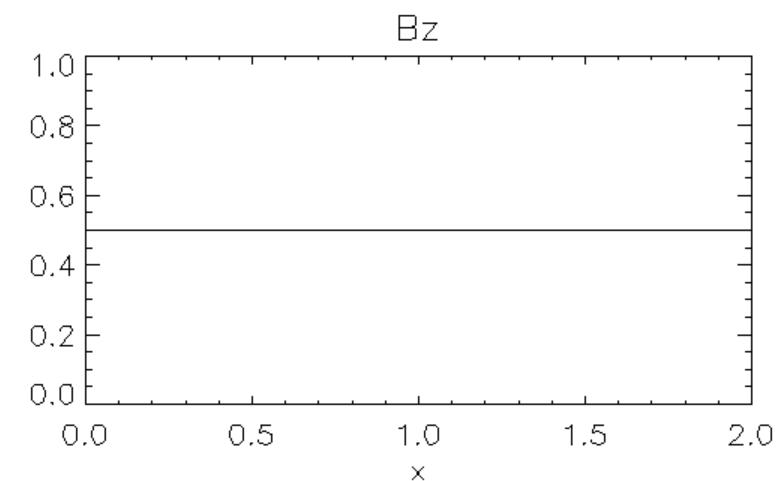

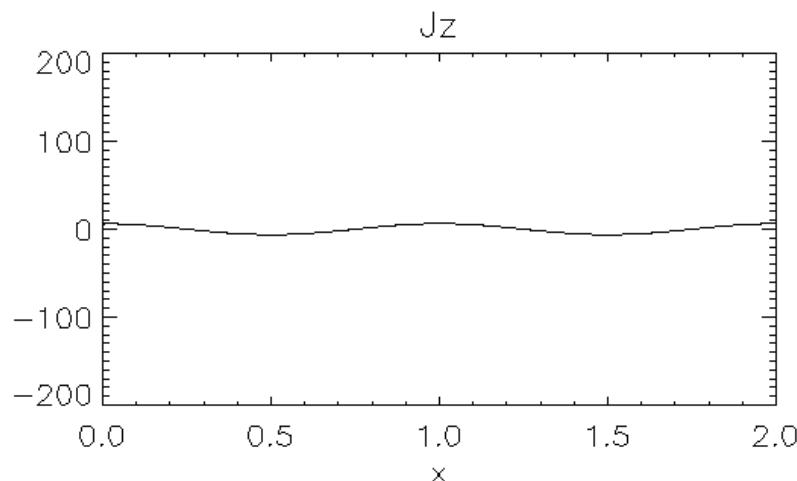

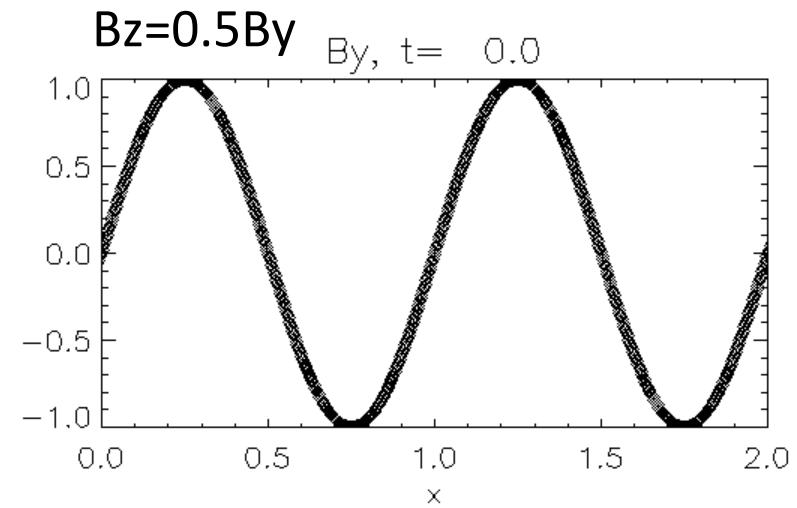

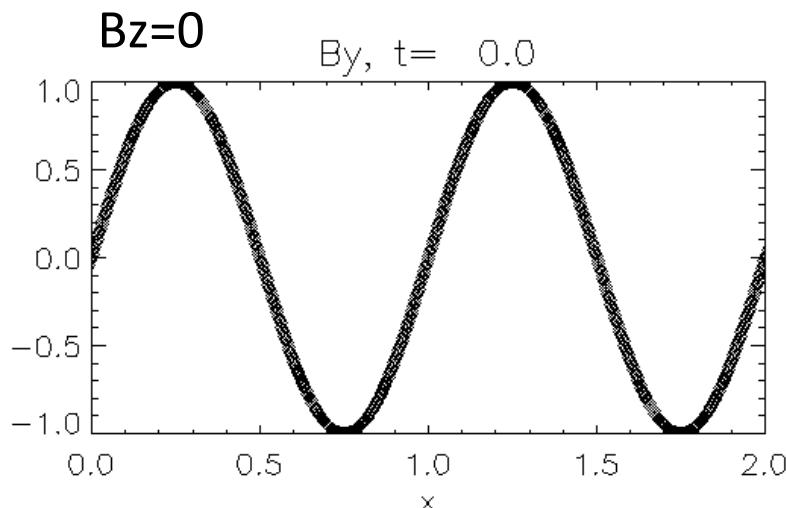

Even though the resistivity is uniform, the localization of ambipolar diffusion causes local thinning of the current sheet, leading to Petschek-like fast reconnection

The “ambipolar layer” almost disappears.

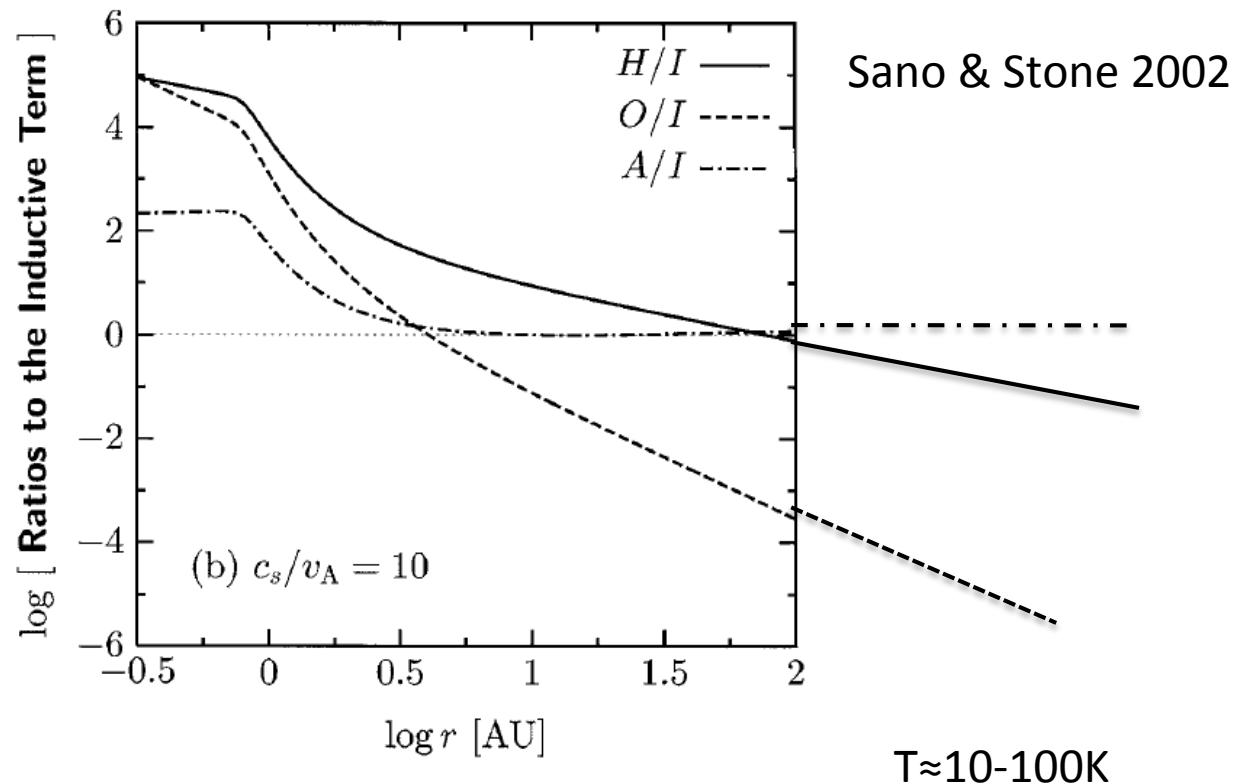

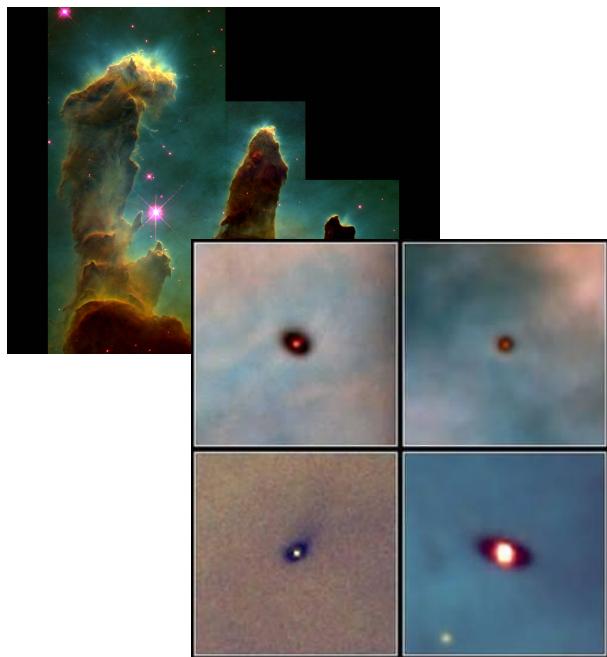

縦磁場の影響

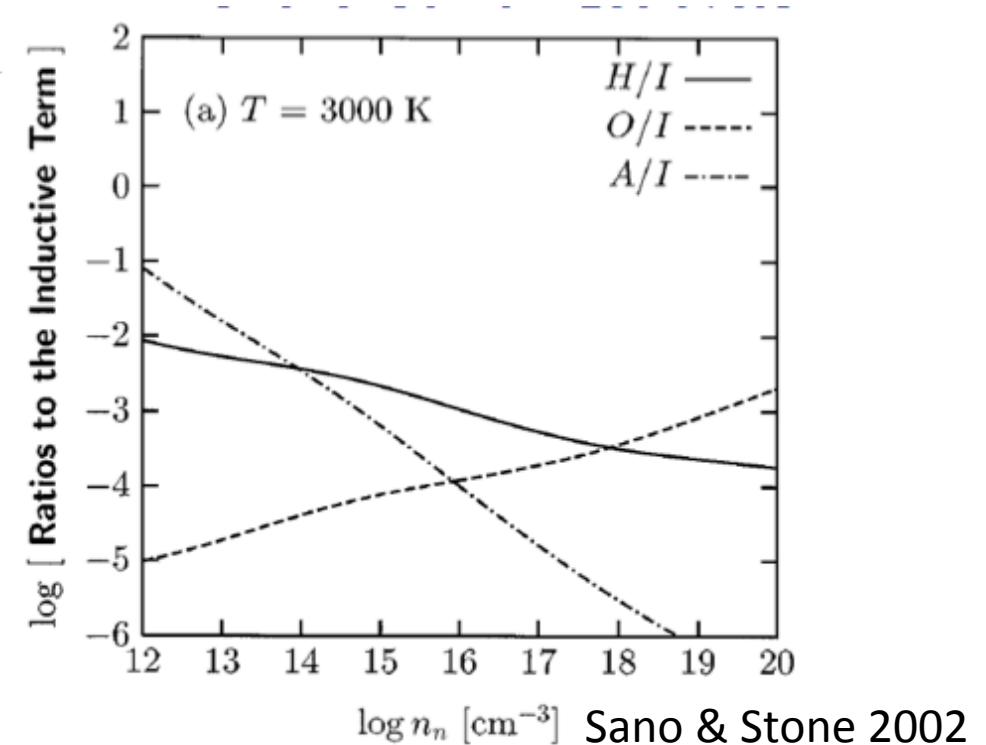

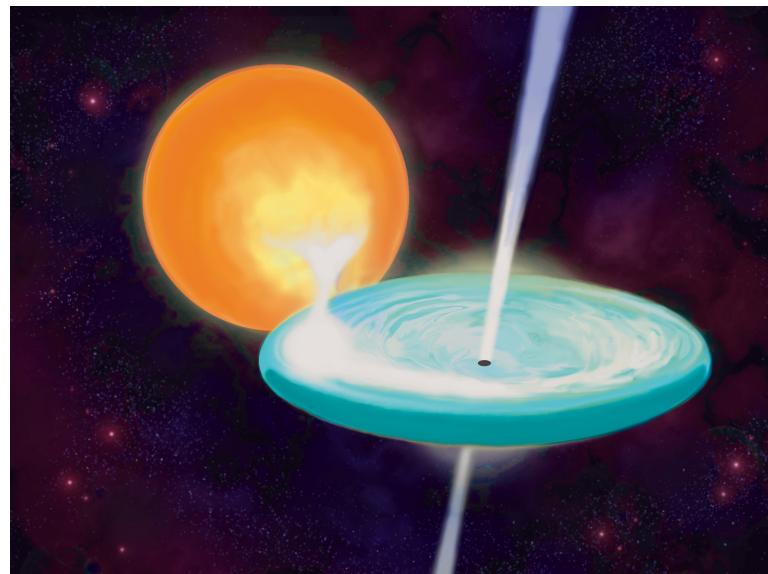

- 縦磁場が強い半暗部やスピキュールの根元などではambipolarは効きにくい
- ただし縦磁場の非一様性が実効的にはambipolar diffusionの局在化と同じ効果を生む...逆に速いリコネクション？

Similar astrophysical plasmas: molecular clouds and protoplanetary disk

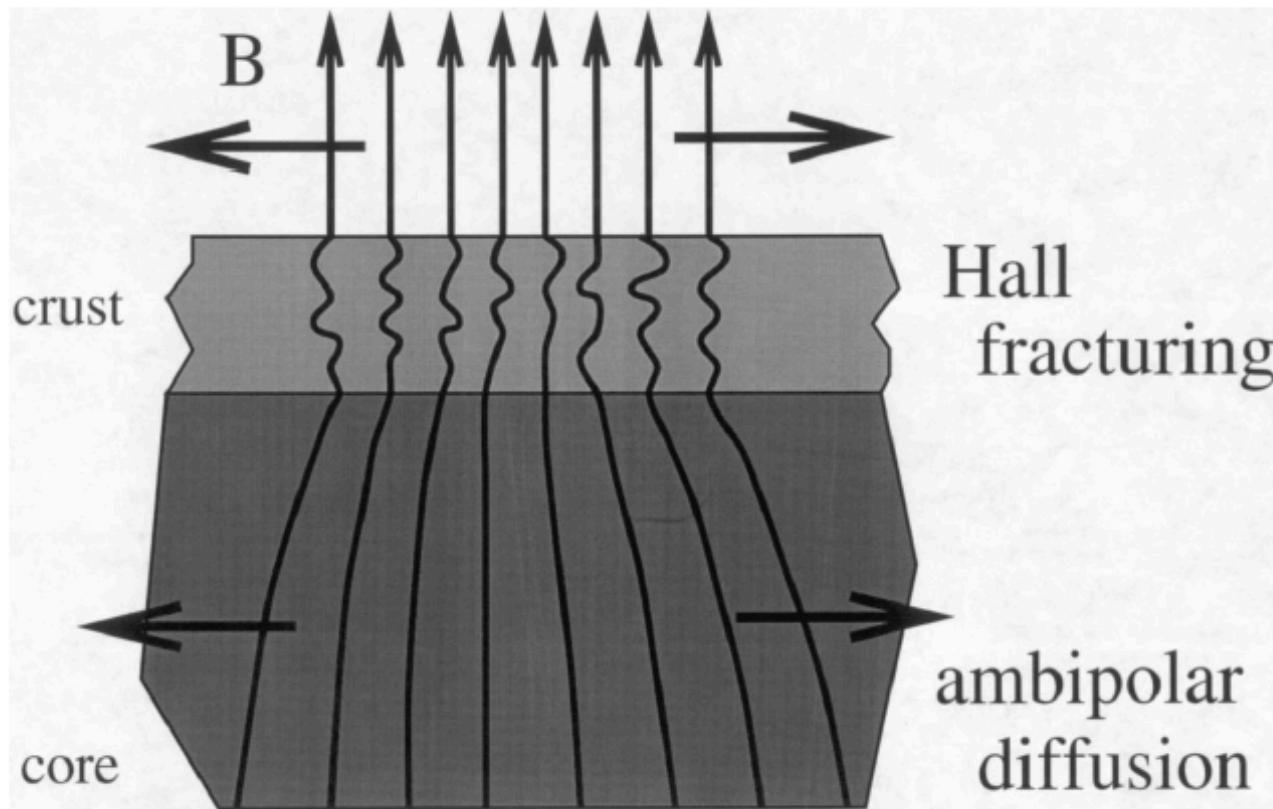

- Hall dominates in inner disk
- Ambipolar dominates in outer disk and molecular clouds
- Dust particles play significant role ... different from sun

Similar astrophysical plasmas: Dwarf nova disk in quiescent phase

- Ambipolar, Hall, and Ohmic terms dominate in inner, middle and outer disk, respectively
- $T > 10^{4-5} \text{ K}$ in outburst phase => fully ionized

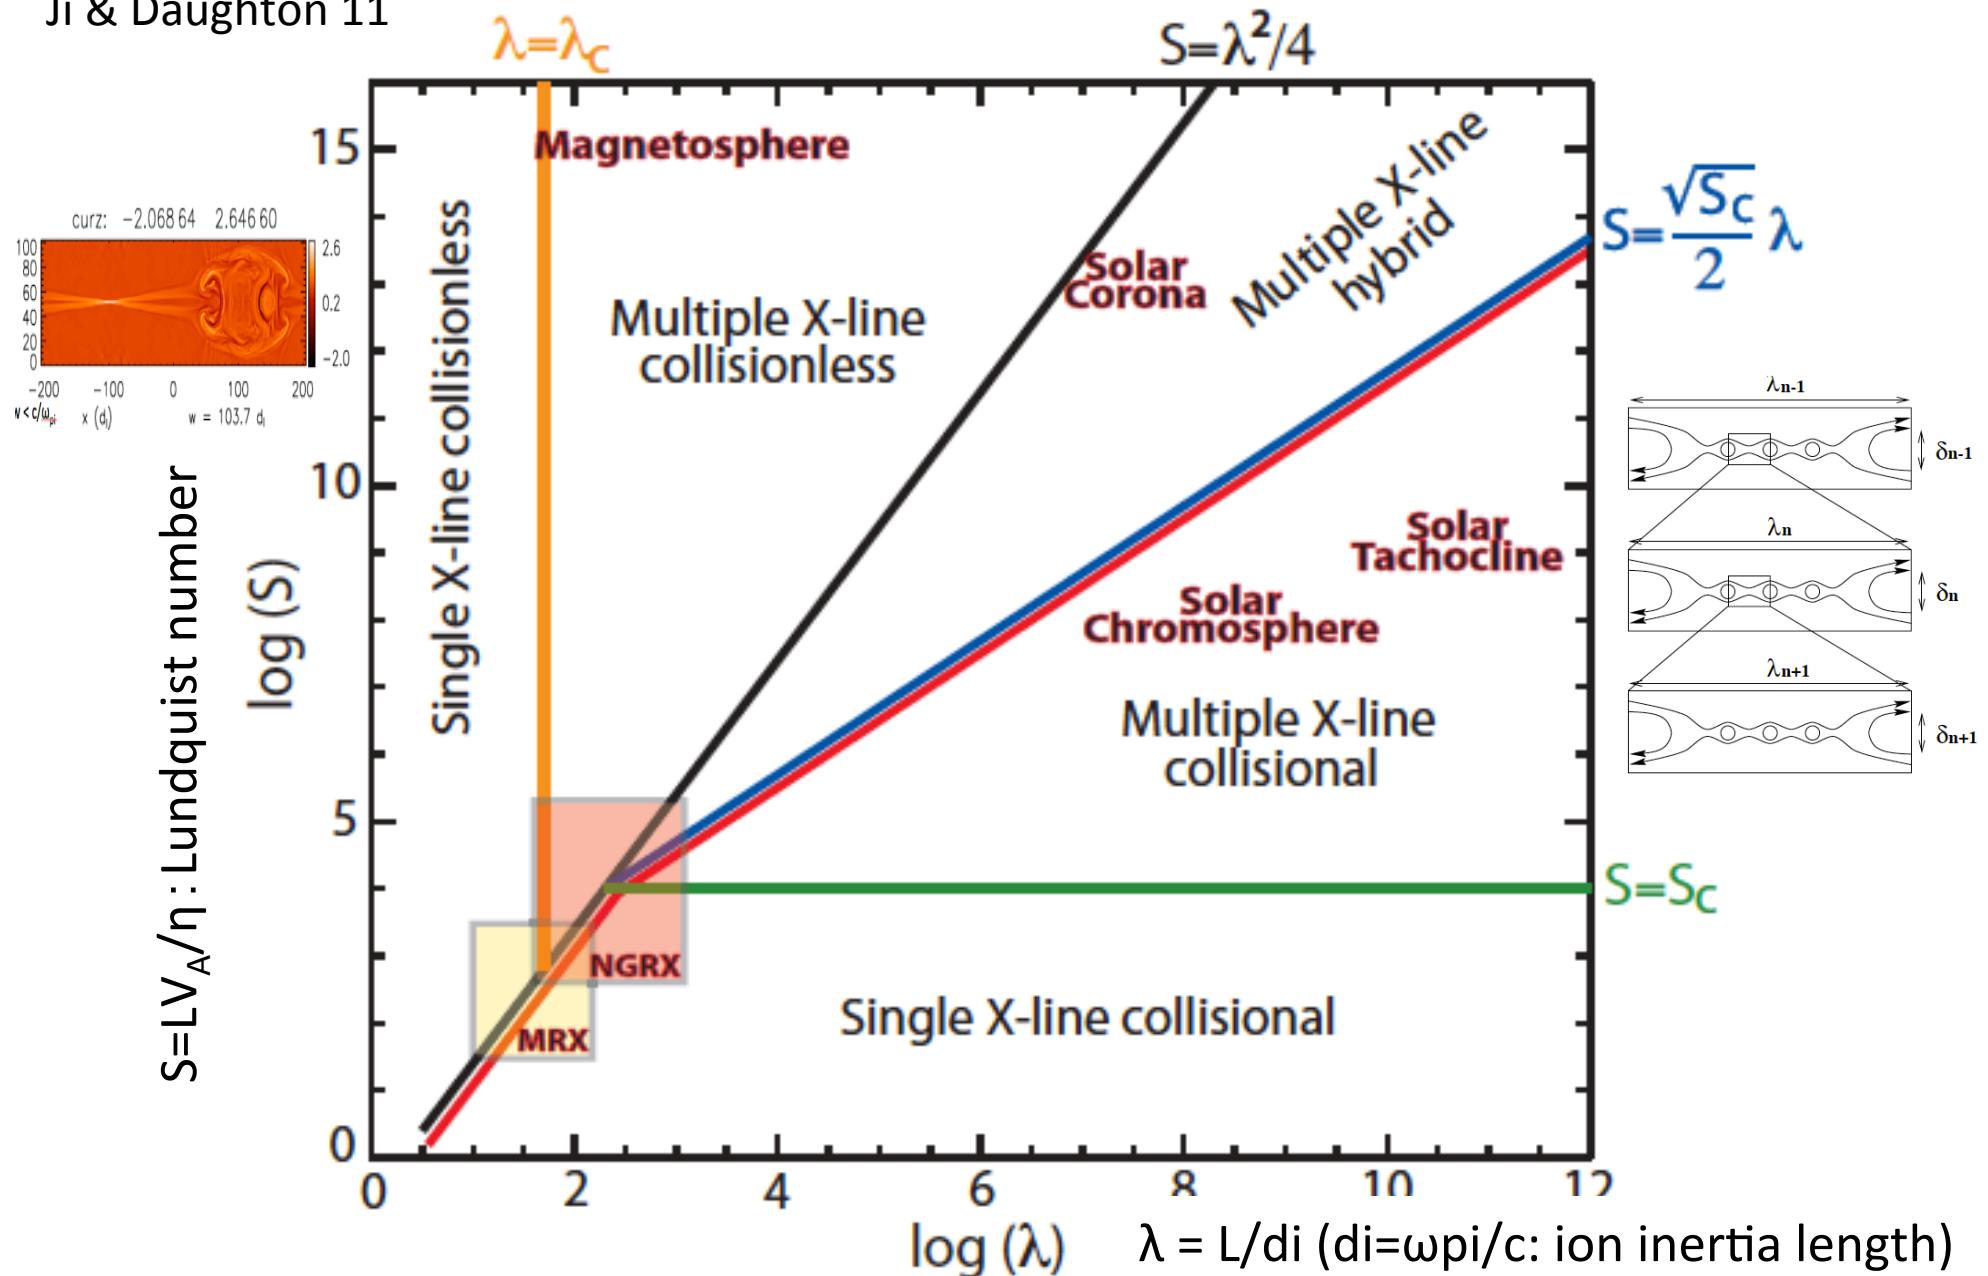

Similar astrophysical plasmas: Interior of neutron star

リコネクション物理の最近の進展(中性の効果はなし)

Ji & Daughton 11

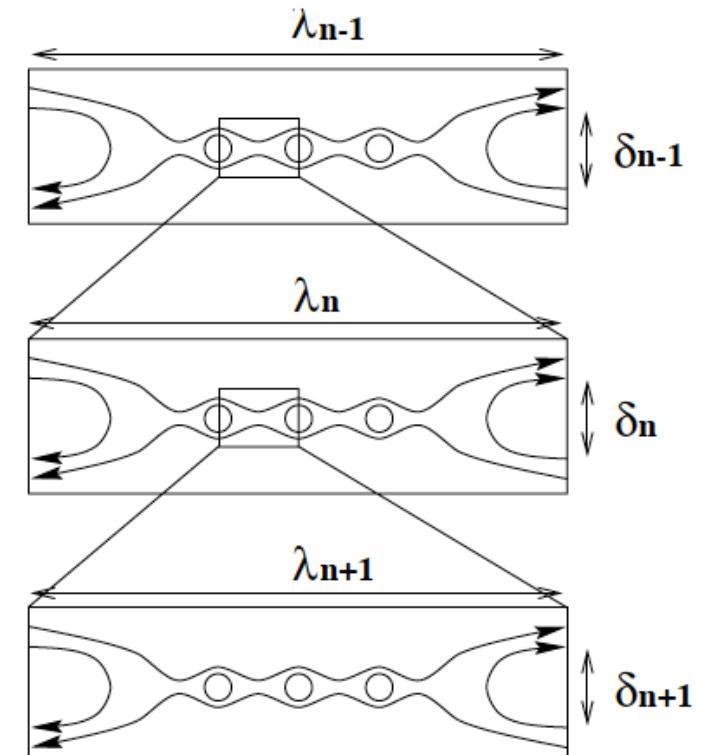

Reconnection with multiple plasmoids/X-lines in High S reconnection

$S = LV_A/\eta = 10^7$ simulation by Samtaney+09

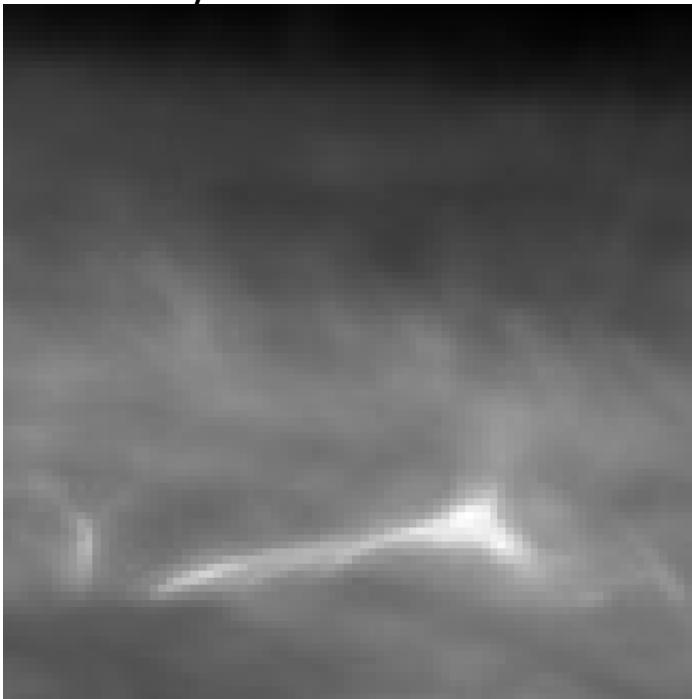

- Multiple islands (plasmoids) by tearing
=> effectively reducing L
=> reconnection faster
- Tearing in reconnecting current sheet
=> further thinning
=> connection to kinetic scales?
- Enhanced reconnection rate with ejection => inherently intermittent

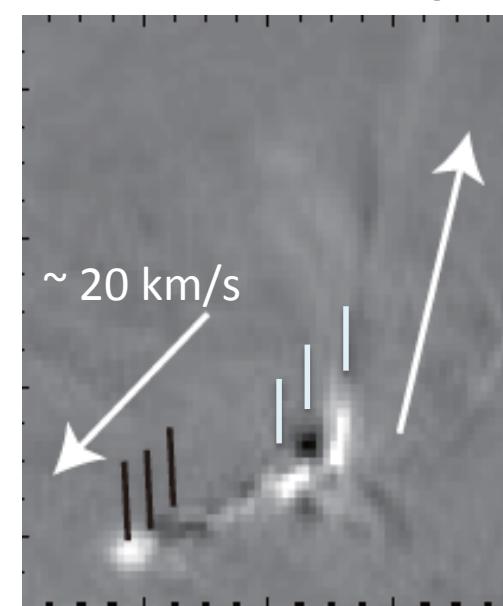

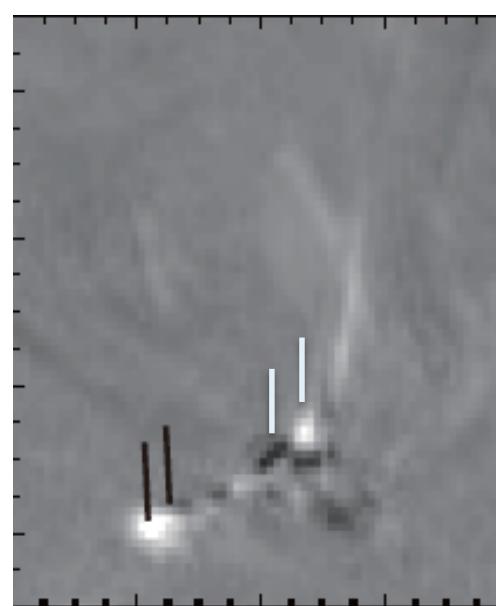

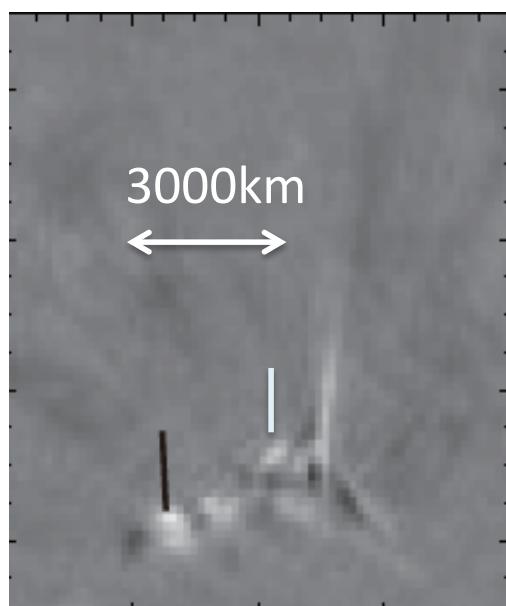

Shibata & Tanuma 01

Hinode/SOT CaH

High-resolution imaging by SOT

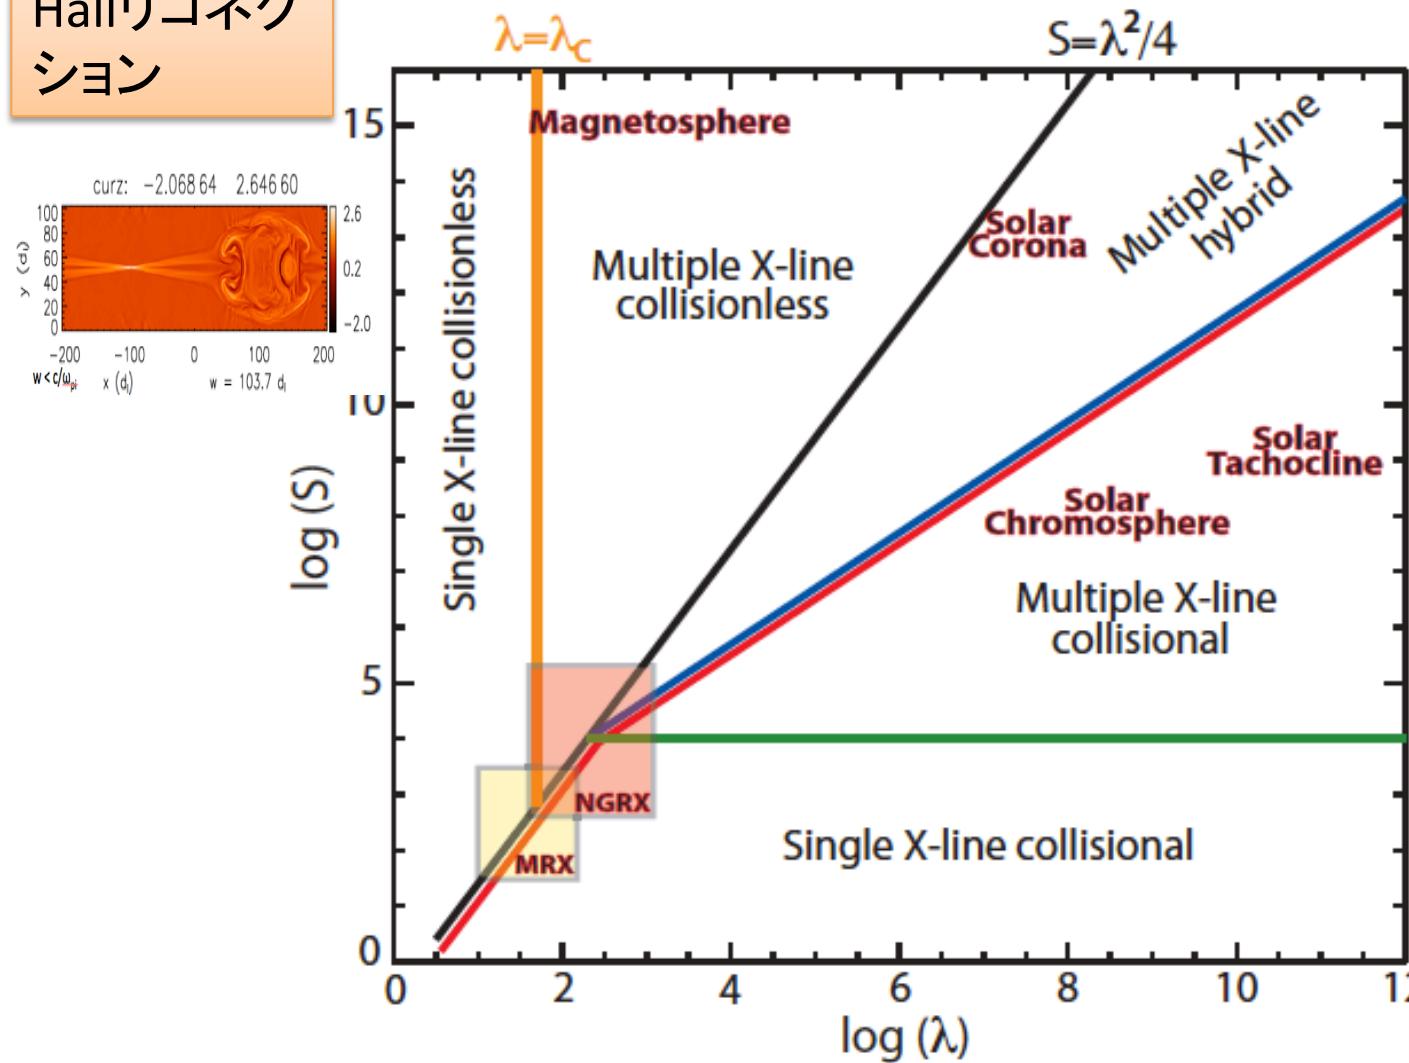

- Reconnection looks bursty
- Multiple plasmoids?

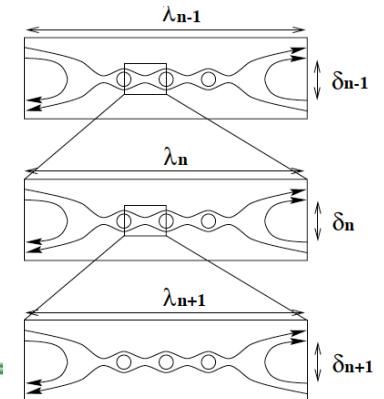

Singh et al. ApJ in press.

ALMAへの期待

- (0.01"分解能切れば)リコネクションのグローバルスケール (~1000km)と散逸スケール(<10km)が初めて見える可能性がある。リコネクション物理にとって極めて重要な観測
- 磁場形状とプラズマパラメータの関数として散逸領域の構造の変化が分かるとさらにすごい
 - 予想:光球はxポイント的、彩層・半平行は小プラズモイドたくさん、縦磁場が強くなるとプラズモイド大きくなるorS-P的
- 電流シートの薄さが<10kmなので、プラズモイドの大きさはもっと大きくなりうる。プラズモイドの大きさ分布などが分かるとたいへん嬉しい
- とにかく高空間分解能が欲しい(0.2"だとちょっと...)。あと、見てる場所の磁場構造とプラズマパラメータ(Solar-Cとのシナジー大)
